Optimal Exchange Rate Policy, Optimal Incomplete Taxation and Business Cycles

Abstract

Implementation and collapse of exchange rate pegging schemes are recurrent events. A currency crisis (pegging) is usually followed by an economic downturn (boom). This essay explains why a benevolent government should pursue fiscal and monetary policies that lead to those recurrent currency crises and subsequent periods of pegging. It is shown that the optimal policy induces a competitive equilibrium that displays a boom in periods of below average devaluation and a recession in periods of above average devaluation. A currency crisis (pegging) can be understood as an optimal policy answer to a recession (boom).

1 Introduction

Implementation and collapse of exchange rate pegging schemes are recurrent events. From Latin America to East Asia, Europe and Africa, several countries have experienced episodes in which pegging schemes were either changed or temporarily abandoned and later reinstated. This research investigates why governments optimally choose to pursue policies that lead to those periodic interventions and subsequent breakdowns.

Previous studies showed that currency crises are frequently followed by a fall below the trend in output and consumption and a real depreciation of the domestic currency. Evidence that the reverse facts plus a deterioration of the current account often accompany a pegging is also available. A model aimed at explaining the recurrent pattern of exchange rate policies should be able to mimic some of that body of empirical evidence. This research also achieved this goal.

The environment studied in this paper is a cash-credit two sector (tradable and non tradable) small open economy without physical capital. This paper builds on Lucas and Stokey’s [24] seminal work on optimal monetary and fiscal policy. The problems of selecting the optimal monetary and exchange rate policies when tax rates are endogenous but not fully state contingent are addressed.

The recurrent pattern of pegging schemes can be easily explained. The optimal policies prescribe a simple behavior for the nominal exchange rate. Despite the fact that the government could successfully pursue a rule of a constant and low devaluation rate, this variable is a non constant function of the economy’s state. Hence, as the state of the economy changes, the devaluation rate oscillates. That will lead to the implementation and collapse of exchange rate pegging policies.
Understanding the links between exchange rate policy and business cycles is more challenging. In periods of high public expenditures, the devaluation will be higher than in other times. The intuition for this finding is simple. In states where government expenditures are relatively high, the optimal policies will prescribe a combination of higher taxation and debt issuing. Since tax rates are not fully state contingent, a possible way to raise additional tax revenue is through inflation. Thus, a higher inflation level will determine a higher rate of devaluation of the domestic currency. A positive technological shock that leads to an output rise will reduce public expenditures as fraction of GDP. Hence, the previous reasoning shows that currency devaluation and technological shocks are negatively correlated.

It is now possible to understand why the model succeeds in mimicking most of the aforementioned stylized facts. For simplicity, assume for a while that tax rates are exogenous. Consider a pegging episode. In response to shocks that decrease the fiscal deficit and increase the productivity, the optimal policy will prescribe a decrease in the devaluation rate. The higher productivity will stimulate the economic activity and lead to higher output. The combination of a lower devaluation rate and a higher output will generate an income effect. Therefore, people will increase their consumption. That increase will be large enough to induce a current account deficit. Since the higher demand for tradables can be partially offset by imports, the real exchange rate appreciates. These are some of the stylized facts associated with a currency peg. In a similar fashion, shocks that increase the fiscal deficit and reduce productivity will lead to a higher devaluation and will induce the empirical regularities associated with a currency crisis.

Most of the stylized facts are indeed reproduced when the taxation is endogenous. The only exception is the behavior of the real exchange rate. The main factor behind this departure from data is that optimal tax rates (other than inflation) are roughly constant. Therefore, public expenditures constitute the only exogenous source of oscillations in the fiscal deficit. Consider a decrease in the nominal devaluation rate. This decrease must be accompanied by a fall in government consumption of non tradables. This will lead to a relatively larger increase in the private consumption of non tradables than of tradables. Since the model’s real exchange rate is a decreasing function of the ratio of people’s consumption of tradables and non tradables, a real depreciation of the domestic currency will take place, contrarily to the pattern displayed in the data.

This paper has some other contributions. Obstfeld [29] states that it is essential to consider how policies are selected to understand currency crises. Rebelo [32] makes similar statements when discussing monetary stabilization. This research helps to understand how the exchange rate policy is chosen.

Exchange rate devaluations are often viewed as a consequence of time consistency.

\footnote{A companion paper shows that oscillations in the public expenditures on tradables will be fully smoothed out through external borrowing and lending. Hence, a change in government consumption of non tradables is required to generate a change in the optimal devaluation rate.}
problems, as in Obstfeld [29] and Giavazzi and Pagano [19]. In this essay, devaluations are fully anticipated and are optimal choices for a government that can credibly commit to a policy.

This research deviates from the approach usually found in the exchange rate crisis literature. It does not rely on arbitrary loss functions for the government. It considers all affordable exchange rate policies, not only the pair floating-pegging.

The paper builds a bridge between two research fields that so far have been seeing as completely apart. Today there is a large and growing body of literature on quantitative macroeconomic theory. Typical examples are the essays of Rebelo [32] and Backus, Kehoe, and Kydland [1]. On the other hand, there exist several studies that rely on reduced form models to explain exchange rate devaluations. Obstfeld [29] and Giavazzi and Pagano [19] are good examples of this investigation avenue. This paper unifies the two approaches.

The essay is organized as follows. A summary of the empirical evidence on exchange rate pegging and currency crisis is presented in section 2. The model is described in section 3. Section 3.1 is devoted to the characterization of competitive equilibria. The problem of selecting policies that lead to the best competitive equilibrium is studied in section 3.2, along with the properties of this efficient outcome. The implications of the model will be compared to some business cycle stylized facts. Section 4 concludes.

2 The Stylized Facts

This section summarizes some previous empirical research on currency pegging and crisis. The available evidence points towards three major empirical regularities:

1. The implementation and collapse of pegging policies are worldwide recurrent events.

2. An exchange rate pegging is accompanied by:

   (a) an increase, relative to trend, in consumption and output;
   (b) a deterioration in the current account;
   (c) an increase in real wages;
   (d) a real appreciation of the exchange rate;
   (e) a reduction in the fiscal deficit.

3. A currency crisis is followed by:

   (a) a decrease, relative to trend, in consumption and output;
   (b) a depreciation of the real exchange rate.
The empirical work of Frankel and Rose [18], Klein and Marion [22], and Milesi-Ferretti and Razin [27] will be briefly reviewed. Each of these essays will be discussed separately. Then, the available evidence will be summed up.

Frankel and Rose [18] used a sample of 104 countries, with annual data from 1971 to 1992. They defined currency crash so that such an event is associated with a depreciation of the domestic currency that is “large” in absolute terms and relative to the previous devaluations. Namely, a currency crash occurred if (i) the nominal exchange rate depreciated at least 25%, (ii) the depreciation rate increased at least 10% compared to the previous year’s value, and (iii) no other depreciation satisfying the first two requirements took place in the last three years. The latter constraint was introduced to avoid double counting. That definition yielded 117 different crashes.

Klein and Marion [22] considered monthly data for 17 Latin American countries from the late 1950’s to the early 1990’s. They found 102 episodes in which a country fixed the exchange rate for at least a month. That averages six fixing policies per country. In a subset of 61 episodes,\(^2\) twelve countries fixed the exchange rate at least three times in the period.

Milesi-Ferretti and Razin [27] studied a sample of 144 countries from 1973 to 1994. They adopted four different notions of currency collapse. For the purpose of this essay, it is enough to look at two of them, CRISIS\(^3\) and CRISIS\(^4\). The former requires (i) a nominal depreciation of at least 15%, (ii) an increase in the devaluation rate of at least 10% when compared to the previous year, (iii) a maximum devaluation of 10% in the year before the crisis, and (iv) no other depreciation satisfying the first three conditions occurred in the last three years. These criteria yielded 136 exchange rate collapses, with 58 taking place in Africa, 33 in Asia, 7 in Europe, and 38 in Latin America. The concept of CRISIS\(^4\) requires (i) the exchange rate to be previously fixed, (ii) the currency to have depreciated in nominal terms at least 15%, and (iii) no other depreciation satisfying the first two requirements having taken place in the last three years. This definition yielded 93 currency crises. Africa underwent 41, Asia 17, Europe 7, and Latin America 28.

That body of empirical evidence makes it clear that governments all around the world often introduce an exchange rate policy (in extreme cases they fix the exchange rate) that will eventually be abandoned. After each collapse the government will sooner or later resume intervention in the currency market.

The evidence provided by Kiguel and Liviatan [21] and Végh [35] will be also reviewed. The conclusions of these studies are widely accepted to the point that Rebelo [32] and Mendoza and Uribe [26] refer to the former authors’ findings as stylized facts.

\(^2\)The geographical distribution of those 61 episodes is presented in table 1 of Klein and Marion [22]. The total figure of 102 fixing events is mentioned shortly before that table. They do not provide the distribution across countries of the remaining 41 episodes. However, the sample is composed of 17 countries. Thus, at least one of them fixed the exchange rate several times.
Kiguel and Liviatan [21] focused on 12 inflation stabilization programs that took place in various countries: Argentina (5), Brazil (2), Chile (1), Israel (1), Mexico (1), and Uruguay (2). These programs were spread over a period from 1959 to 1992. Half of them fixed the nominal exchange rate. The other half relied on a combination of fixing, periodical devaluations, preannounced devaluations or crawling peg. All of the programs were eventually accompanied by an increase (relative to trend) in real GDP. In ten programs there was a consumption boom. The current account deteriorated in all programs. Real wages did not increase only in three. With one exception, all programs were followed by a real exchange rate appreciation. Finally, ten programs were accompanied by a reduction in the fiscal deficit.

Végh [35] investigated ten of the twelve episodes studied by Kiguel and Liviatan [21]. He concluded that devaluation, consumption, real exchange rate, and current account followed the pattern described by the other two researchers.

Concerning exchange rate crisis and business cycle, Milesi-Ferretti and Razin [27] found evidence that currency crises are followed by a growth slowdown for output and consumption and a real depreciation of the domestic currency. Frankel and Rose [18] also verified that output generally falls below the trend after an exchange rate collapse.

3 The Economy

Consider a small country populated by a continuum of identical infinitely lived households with Lebesgue measure one and a government. A household is composed by a shopper and a worker, who is endowed with one unit of time.

That country produces two non tradable goods. The first is consumed by households \( (c^N_1) \). The second is consumed by households \( (c^N_2) \) and government \( (g^N) \). The country also produces a tradable good, which is consumed by households \( (c^T) \) and a government \( (g^T) \). This last good can also be exported \( (x) \) or imported \( (-x) \).

Transactions take place in this economy in a particular way. At a first stage of each date \( t \) spot markets for goods and labor services operate. At the second stage, security and currency markets operate.

A domestic currency \( M \) circulates in this economy. Two types of securities are traded: a claim \( B \), with maturity of one period, to one unit of \( M \) and a claim \( B^* \), with the same maturity, to one unit of some foreign currency. Foreigners do not sell or buy claims to the domestic currency. Government and residents can purchase and/or sell the claims \( B^* \) at an exogenous price, in terms of the foreign currency, \( q^* \).

Workers cannot sell their services outside the country. Shoppers face a cash-in-advance constraint. The purchases of \( c^N_1 \) must be paid for with the domestic currency. Except for the purchases of that good, all other transactions are liquidated during the security and currency trading session. The date \( t \) price, in terms of the foreign currency, of the tradable good is exogenous and equal to \( p^*_T \).
Technology is described by $0 \leq y^T \leq \theta^T(l^T)^{\alpha^T}$ and $0 \leq y^N \leq \theta^N(l^N)^{\alpha^N}$, where $y^T$ is the tradable output and $l^T$ is the amount of labor allocated to the production of that good. A similar meaning is assigned to $y^N$ and $l^N$. Both $\alpha^T$ and $\alpha^N$ lie in the set $(0, 1]$.

Let $s_t = (\theta^T_t, \theta^N_t, g^T_t, g^N_t, p^*_t, q^*_t)$. The sequence $\{s_t\}^\infty_{t=0}$ is a stochastic process on some probability space $\Omega, \mathcal{F}, P$. Each $s_t$ has a support contained in the finite set $S = \Theta^T \times \Theta^N \times G^T \times G^N \times P^* \times Q^*$. These sets satisfy $\Theta^T \subset \mathbb{R}_{++}$, $\Theta^N \subset \mathbb{R}_{++}$, $G^T \subset \mathbb{R}_+$, $G^N \subset \mathbb{R}_+$, $P^* \subset \mathbb{R}_{++}$, and $Q^* \subset (0, 1)$. The object $s^t$ stands for a history $(s_0, ..., s_t)$ of events and $s^\infty = (s_0, s_1, ...)$. The sets $S^t$ and $S^\infty$ are standard Cartesian products.

For a given $s^t$ in $S^t$, $\mu(s^t)$ denotes the probability that the first $t$ realizations of the process will be equal to $s^t$. The realization of $s_t$ is known at the beginning of date $t$. If $k \leq t$, $\mu(s^t|s^k)$ denotes the conditional probability of $s^t$ given $s^k$; $S^t(s^k)$ is the set of all $s^t \in S^t$ such that the first $k$ events in $s^t$ are equal to $s^k$. In other words, $S^t(s^k)$ is the set of all possible continuations of the history $s^k$ up to date $t$. Whenever there is no danger of confusion, $S^t(s^k)$ will be denoted by $S^t_k$. As usual, $\{\mu(s^t)|s^t \in S^t\}^\infty_{t=0}$ is a history contingent sequence. Define

$$||a||_{\infty} = \sup_{t} \sup_{s^t \in S^t} |a(s^t)| . \quad (1)$$

Each good is produced by a single competitive firm. Let $l(s^t)$ denote the amount of labor supplied by each household at date $t$ if the history $s^t$ occurs. Other variables indexed by $s^t$ have analogous meaning. Feasibility requires

$$l^T(s^t) + l^N(s^t) = l(s^t) \leq 1 , c^N_1(s^t) + c^N_2(s^t) + g^N_t = \theta^N [l^N(s^t)]^{\alpha^N},$$

$$c^T(s^t) + g^T_t + x(s^t) = \theta^T [l^T(s^t)]^{\alpha^T}. \quad (2)$$

The government finances the sequence $\{g^T_t, g^N_t\}^\infty_{t=0}$ by issuing and withdrawing the domestic currency; by issuing and redeeming claims $B$ of maturity of one period to one unit of the domestic currency; by purchasing and selling $B^*$; and taxing labor income at a proportional tax $\tau$. The date zero tax rate is exogenous and equal to some value $\tau_0$. At other periods, that variable depends on the history $s^t+1$ but it must satisfy the constraint

$$\tau(s^t, s_{t+1}) = \tau(s^t, \bar{s}_{t+1}), \forall s^t, s_{t+1}, \bar{s}_{t+1} . \quad (3)$$

The government budget constraint is

$$E(s^t)p^*_tg^T_t + p^N(s^t)g^N_t + B(s^{t-1}) + E(s^t)q^*_tB^*_G(s^t) + M(s^{t-1}) =$$

$$\tau(s^t)w(s^t)l(s^t) + q(s^t)B(s^t) + E(s^t)B^*_G(s^{t-1}) + M(s^t) , \quad (4)$$

where $p^N(s^t)$, $w(s^t)$ and $q(s^t)$ are the respective date $t$ monetary prices (in terms of the domestic currency) of the non tradable good, labor services and the domestic currency, respectively.
where $\beta$ is the initial amount that the government is borrowing abroad, while a negative value for $B(s^t)$ means that the government is lending to domestic residents. At $t = 0$ the government holds an initial amount $B^*_G$ of foreign assets. To avoid Ponzi schemes, a standard boundedness constraint $\|B_G^*/p^*\|_\infty \leq A < \infty$ is imposed on the government foreign assets.

The function $u : \mathbb{R}_+^3 \times [0, 1] \to \mathbb{R} \cup \{-\infty\}$,

$$u(c^T, c^N_1, c^N_2, l) = \frac{\left[ (c^T)^\gamma (c_1^N)^{\gamma_1} (c_2^N)^{\gamma_2} (1 - l)^{\gamma^T} \right]^{1-\sigma}}{1 - \sigma},$$

is the typical household period utility function. As usual, the $\gamma$’s are positive and add up to 1, while $\sigma \geq 0$. Intertemporal preferences are described by

$$\sum_{t=0}^{\infty} \sum_{s^t \in S^1} \beta^t \mu(s^t) u(c^T(s^t), c^N_1(s^t), c^N_2(s^t), l(s^t)),$$

where $\beta \in (0, 1)$. The date $t$ budget constraint of the typical household is

$$E(s^t) p^*_t c^T(s^t) + p^N(s^t) [c^N_1(s^t) + c^N_2(s^t)] + q(s^t) B(s^t) +$$

$$E(s^t) q^*_t B^*_H(s^t) + M(s^t) \leq [1 - \tau(s^t)] w(s^t) l(s^t) + B(s^{t-1}) +$$

$$E(s^t) B^*_H(s^{t-1}) + M(s^{t-1}) + \psi^T(s^t) + \psi^N(s^t),$$

where $B^*_H(s^t)$ stands for the foreign assets held by the household at the end of date $t$ if history $s^t$ occurs and $\psi^T(s^t)$ and $\psi^N(s^t)$ are the date $t$ profits. The constraint $\|B/p^N\|_\infty, \|B_H^*/p^*\|_\infty \leq A$ prevents Ponzi games. People face the cash-in-advance constraint

$$p^N(s^t) c^N_1(s^t) \leq M(s^{t-1}).$$

Given initial asset holdings $(\bar{M}, \bar{B}, \bar{B}_H^*)$, a household chooses a history contingent sequence $\{(c^T(s^t), c^N_1(s^t), c^N_2(s^t), l(s^t), B(s^t), B_H^*(s^t))_{s^t \in S^1}\}_{t=0}^\infty$ to maximize (6) subject to the constraints (7), (8), and $l(s^t) \leq 1$. Except for $B(s^t)$ and $B_H^*(s^t)$, all those variables are constrained to be non-negative. An additional boundedness condition $\|c^T\|_\infty, \|c^N_1\|_\infty, \|c^N_2\|_\infty, \|l\|_\infty, \|M/p^N\|_\infty < \infty$ is imposed on the consumer problem.

Adding the identities $\psi^N(s^t) + w(s^t) l^N(s^t) = p^N(s^t) [c^N_1(s^t) + c^N_2(s^t) + g^N]$ and $\psi^T(s^t) + w(s^t) l^T(s^t) = E(s^t) p^*_t [c^T(s^t) + g^T + x(s^t)]$ to (4) and (7) taken as equality, one obtains

$$p^*_t x(s^t) + B^*_G(s^{t-1}) + B^*_H(s^{t-1}) - q^*_t B^*_G(s^t) - q^*_t B^*_H(s^t) = 0,$$

which is the balance-of-payments identity.
3.1 Competitive Equilibrium

A history contingent date $t$ policy $(E(s^t), p^N(s^t), w(s^t), q(s^t), B^*_H(s^t), \tau(s^t))$ is denoted by $\varphi(s^t)$. A policy is a history contingent sequence $\varphi = \{[\varphi(s^t)]_{s^t \in S^t}\}_{t=0}^\infty$. Date $t$ history contingent allocations $(c^T(s^t), c_1^N(s^t), c_2^N(s^t), l(s^t), \tau^N(s^t), \tau(s^t), x(s^t))$ and asset holdings $(M(s^t), B(s^t), B^*_H(s^t))$ are denoted, respectively, by $\chi(s^t)$ and $\phi(s^t)$. Additionally, $\chi = \{[\chi(s^t)]_{s^t \in S^t}\}_{t=0}^\infty$ and $\phi = \{[\phi(s^t)]_{s^t \in S^t}\}_{t=0}^\infty$.

**Definition 1** A competitive equilibrium is an object $(\varphi, \chi, \phi)$ that satisfies the following properties: (i) given prices, $(\chi, \phi)$ provides a solution for the household problem; (ii) $w(s^t) = p^N(s^t)\alpha_s^N\theta^N_1[1^N(s^t)]^{\alpha_s^N-1} = E(s^t)p^*_t\alpha^T_t\theta^T_t[1^T(s^t)]^{\alpha^T_t-1}$; (iii) (2), (3), and (4) hold.

The definition of competitive equilibrium does not place bounds on inflation. For future reference, it is convenient to spell out a particular boundedness requirement.

**Definition 2** A competitive equilibrium $(\varphi, \chi, \phi)$ is of bounded inflation if

$$\exists \varepsilon > 0 : \varepsilon \leq \frac{p^N(s^t, s_{t+1})}{p^N(s^t)} \leq \frac{1}{\varepsilon}, \forall s^\infty \in S^\infty, \forall t. \quad (10)$$

The above condition prevents prices from increasing or decreasing “too much” in a single period.

The government can pursue several distinct policies. To clarify this point, consider the simple case in which the government has no source of revenue but inflation. For simplicity, assume that at date zero the government has no net debt and the public consumption is always positive. The government can balance its lifetime budget with a constant inflation rate and borrow abroad to finance temporary imbalances. It is also possible to balance the budget period by period solely with inflation tax. In this case the inflation does not need to be constant. Different policies will induce distinct competitive equilibria. In this section a set of competitive equilibrium allocations will be characterized. That will reduce the problem of selecting an efficient policy to a standard constrained maximization problem.

To simplify the notation, $u(s^t)$, $u_T(s^t)$, $u_1(s^t)$, $u_2(s^t)$, and $u_i(s^t)$ will denote, respectively, the value of $u$ and its partial derivatives $\partial u / \partial c^T$, $\partial u / \partial c^N_1$, $\partial u / \partial c^N_2$, and $\partial u / \partial l$ evaluated at the point $(c^T(s^t), c_1^N(s^t), c_2^N(s^t), l(s^t))$. The auxiliary variable $W(s^t)$ is defined according to

$$W(s^t) = \{\alpha^T c^T(s^t) - (1 - \alpha^T)\tau(s^t) + g^T_t\} u_T(s^t) + u_1(s^t)c_1^N(s^t) +$$

$$\{\alpha^N c_1^N(s^t) - (1 - \alpha^N)\tau(s^t) + g^N_t\} u_2(s^t) + u_i(s^t)l(s^t) .$$

3Throughout this essay the term inflation will apply to the rate of increase in $p^N$. 

8
There exist seven constraints with obvious economic meaning that must hold in any competitive equilibrium. A trivial condition is (2). The second is
\[ \sum_{t=0}^{\infty} \sum_{s^t \in S} \beta^t \mu(s^t) W(s^t) = u_1(s^0) c_N^1(s^0) + \]
\[ u_2(s^0) \left[ \frac{B}{p^N(s^0)} + \frac{M}{p^N(s^0)} - c_N^1(s^0) \right] + u_T(s^0) \frac{B^*_H}{p^*_0} , \quad (11) \]
which is simply the consolidation of all date \( t \) budget constraints of the households. The third is a balance-of-payment constraint
\[ - \sum_{t=0}^{\infty} \sum_{s^t \in S} \beta^t \mu(s^t) u_T(s^t) x(s^t) = u_T(s^0) \frac{B^*_H + B^*_G}{p^*_0} , \quad (12) \]
which requires imports to be financed by the country’s initial wealth. The fourth requirement, ensuring that people’s marginal rate of substitutions are consistent with the international interest rates and prices, is
\[ q^*_t \mu(s^t) \frac{u_T(s^t)}{p^*_t} = \beta \sum_{s_{t+1} \in b_{t+1}} \frac{\mu(s^t, s_{t+1}) u_T(s^t, s_{t+1})}{p^*_{t+1}} . \quad (13) \]
The fifth constraint is that households’ marginal rate of substitution between tradables and non tradables must match the marginal rate of transformation between those types of goods, i.e.,
\[ \frac{u_T(s^t)}{u_2(s^t)} = \frac{\alpha^N \theta^N_t [l^T(s^t)]^{1-\alpha^T}}{\alpha^T \theta^T_t [l^N(s^t)]^{1-\alpha^N}} . \quad (14) \]
This equation is also an implementability condition for the real exchange rate \( \frac{E(s^t)}{p^N(s^t)} \).

The sixth
\[ \frac{u_1(s^t, s_{t+1})}{u_2(s^t, s_{t+1})} \frac{[l^N(s^t, s_{t+1})]^{1-\alpha^N}}{\alpha^N \theta^N_{t+1}} = \frac{u_1(s^t, \bar{s}_{t+1})}{u_2(s^t, \bar{s}_{t+1})} \frac{[l^N(s^t, \bar{s}_{t+1})]^{1-\alpha^N}}{\alpha^N \theta^N_{t+1}} , \quad (15) \]
is an implementability constraint for (3), while
\[ (1 - \tau_0) \frac{\alpha^N \theta^N_0}{[l^N(s^0)]^{1-\alpha^N}} = - \frac{u_1(s^0)}{u_2(s^0)} , \quad (16) \]
enforces that the allocations are consistent with \( \tau_0 \).

The above constraints are not enough to characterize a competitive equilibrium. Seven other conditions have to be imposed. The inequalities
\[ p^N(s^0) c_N^1(s^0) \leq \tilde{M} \quad (17) \]
ensure that cash-in-advance constraints hold. An implementability constraint for a transversality condition is

$$\lim_{t \to \infty} \beta^t \sum_{s^t \in S^t} \mu(s^t) u_1(s^t) c_1^N(s^t) = 0.$$  

The boundedness of foreign debt requires

$$\sup_k \sup_{s^k \in S^k} \frac{1}{u_2(s^k)} \left| \sum_{t=k}^{\infty} \sum_{s^t \in S^t} \beta^{t-k} \mu(s^t | s^k) w_T(s^t) x(s^t) \right| < \infty.$$  

A similar constraint is required to ensure that \( \| B/p^N \|_\infty < \infty \). However, it is not possible to characterize that condition for all competitive equilibria. Nevertheless, it is possible to do so for all equilibria with bounded inflation. If the inflation is bounded, it is enough to require

$$\sup_k \sup_{s^k \in S^k} \frac{1}{u_2(s^k)} \left| \sum_{t=k}^{\infty} \sum_{s^t \in S^t} \beta^{t-k} \mu(s^t | s^k) w_T(s^t) x(s^t) - u_1(s^k) c_1^N(s^k) \right| < \infty.$$  

Inflation is bounded if there exists a positive \( \varepsilon \) such that

$$\varepsilon \leq \frac{\beta}{\mu(s^t) u_2(s^t)} \sum_{i_{t+1} \in \mathcal{S}} \mu(s^t, \hat{s}_{t+1}) u_1(s^t, \hat{s}_{t+1}) \frac{c_1^N(s^t, \hat{s}_{t+1})}{c_1^N(s^t, s_{t+1})} \leq \frac{1}{\varepsilon}.$$  

As in definition 2, \( \varepsilon \) does not depend on the histories.

In a longer version of this essay, the following result was established.

**Proposition 1 (a set of competitive equilibria)** Let \( \bar{M} > 0 \). An array \( \chi \) and a price \( p^N(s^0) > 0 \) satisfy (2) and (11)-(22) if and only if they are components of a competitive equilibrium \((\varphi, \chi, \phi)\) of bounded inflation.

### 3.2 Ramsey Equilibrium

#### 3.2.1 Definition and Characterization

As mentioned before, the concept of competitive equilibrium does not impose optimality on the government behavior. In this section, a game in which the government is a player will be considered.

At date zero, before markets open, the government announces that will follow a policy \( \varphi \). That policy cannot be changed in future dates (i.e., there is some commitment device that allows the government to credible stick to \( \varphi \)). Then, private agents
will be allowed to trade. The government is benevolent and will choose $\phi$ to maximize
(6).

Private agents actions depend on the prevailing policy. To keep track of that
relation, let $f$ denote a generic function that maps a vector $(s^t, \varphi)$ into the space
of the pairs $(\chi(s^t), \phi(s^t))$. As before, $f(\varphi) = \{f(s^t, \varphi)\}_{s^t \in S^t}$. Abusing the notation,
$u(f(s^t, \varphi))$ will denote $u$ evaluated at the corresponding $(c^T(s^t), c^N_1(s^t), c^N_2(s^t), l(s^t))$
coordinates of $f(s^t, \varphi)$.

**Definition 3** A Ramsey equilibrium is a pair $(\varphi, f)$ satisfying: (i) for all $\bar{\varphi}$, $f(\bar{\varphi})$
provides solutions for both households’ and firms’ problems; (ii) the policy $\varphi$ solves
$\max_{\phi} \sum_{t=0}^{\infty} \sum_{s^t \in S^t} \beta^t u(f(s^t, \varphi))$ subject to (2), (4) and (3). A triple $((\varphi,\chi,\phi))$
consists in choosing paths for money supply, domestic debt, external borrowing, and
no matter the chosen policy. So, government uses this information when choosing
\phi. Note that this requirement is equivalent to subgame perfection, as pointed out by
Chari and Kehoe [13].

Recall that $\{g^T_t, g^N_t\}_{t=0}^{\infty}$ is a stochastic process. Thus, the government
problem consists in choosing paths for money supply, domestic debt, external borrowing, and
tax rates to maximize people’s welfare. One can see this problem as a simplified
version of the problem faced by a benevolent government that takes the expenditures
as given and it is not able to design tax rates that are fully state contingent.

In a Ramsey equilibrium, the government chooses a policy that will maximize
people’s welfare. It is possible to characterize Ramsey outcomes through a standard
maximization problem. For this particular model, the result is stated below.

**Proposition 2** Suppose that $(p^N(s^0), \chi)$ solves

$$\max_{(p^N(s^0), \chi)} \sum_{t=0}^{\infty} \sum_{s^t \in S^t} \beta^t u(c^T(s^t), c^N_1(s^t), c^N_2(s^t), l(s^t))$$

subject to (2) and (11)-(16). If $(p^N(s^0), \chi)$ satisfies (17)-(22), then $(p^N(s^0), \chi)$ is a
component of some Ramsey outcome $(\varphi, \chi, \phi)$.

**3.2.2 Examples**

In all incoming examples it is assumed that $B = B^*_T = B^*_H = 0$, $s^0 = a$, $\tau_0 = 20\%$,
p^*_1 = 1, q^*_t = $\beta$ and $g^T_t = 0$. The sequence $\{g^N_t, \theta^N_t, \theta^T_t\}_{t=0}^{\infty}$ is a Markov process on
the state set $\{a, b\}$ with transition probabilities $\mu_{ab}$ and $\mu_{ba}$. The period utility is
$u = (c^T)^{\gamma_t}(c^N_1)^{\gamma_1}(c^N_2)^{\gamma_2}(1-l)^{\gamma_1}$. State space and transition probabilities are example
specific. A detailed explanation of how to compute the optimal allocations is provided
in a longer version of this essay.
Example 1 (benchmark economy: the optimal policies) The current example will be adopted as a benchmark to the next ones. The state space satisfies $\theta_t^N = \theta_t^T = 1$, $g_a^N = 0.05$, and $g_b^N = 0.1$. The transition probabilities are $\mu_{ab} = 0.4$ and $\mu_{ba} = 0.7$. Let $\dot{E}$ denote the rate of devaluation of the nominal exchange rate. The optimal policies are described by

$$
(\dot{E}(s^t), \tau(s^t)) = \begin{cases} 
(13.20\%, 20.78\%) & \text{if } (s_t, s_{t+1}) = (a, a); \\
(20.41\%, 20.78\%) & \text{if } (s_t, s_{t+1}) = (a, b); \\
(13.65\%, 20.86\%) & \text{if } (s_t, s_{t+1}) = (b, a); \\
(20.88\%, 20.86\%) & \text{if } (s_t, s_{t+1}) = (b, b).
\end{cases}
$$

Tax rates are roughly constant. Whenever the economy hits state $b$ (the state with higher government consumption) the domestic currency devaluates almost 21%, while in state $a$ the devaluation is close to 13.5%.

In the above example the consumption is higher in state $a$ when compared to consumption in state $b$. Output displays the opposite behavior. The empirical evidence mentioned in section 2 states that in periods of higher devaluation both output and consumption fall and in periods of pegging these two variables grow faster. Thus, example 1 fails to reproduce some of the quantitative features found in the data. This is a general feature of the model. An economy driven only by fiscal shocks cannot account for all patterns found in the real data.

Several alternative policies could be implemented as a competitive equilibrium. To illustrate some of these possibilities, three alternative policies will be presented below.

Example 2 (benchmark economy: the Friedman Rule) The policies

$$
(\dot{E}(s^{t+1}), \tau(s^{t+1})) = \begin{cases} 
(-2.05\%, 25.78\%) & \text{if } (s_t, s_{t+1}) = (a, a); \\
(2.35\%, 25.78\%) & \text{if } (s_t, s_{t+1}) = (a, b); \\
(-1.62\%, 25.78\%) & \text{if } (s_t, s_{t+1}) = (b, a); \\
(2.80\%, 25.78\%) & \text{if } (s_t, s_{t+1}) = (b, b);
\end{cases}
$$

can be implemented in the benchmark economy. The associated allocations satisfy $u_1(s^t) = u_2(s^t)$. This condition implies that the $q(s^t) = 1$, that is, the nominal interest rate is zero. This is exactly the well known Friedman Rule.\footnote{For a discussion of the Friedman Rule, see [11] or [17].}

The fact that the Friedman Rule can be implemented in this economy but it is not optimal is, at first glance, surprising. The economy is a two sector cash-credit good one. In an one sector cash-credit good closed economy environment the Friedman Rule is known to be optimal.

An obvious reason, in this environment, to depart from the Friedman Rule is the incomplete taxation feature. However, it is possible that it is not the only cause. For
instance, the optimality of the Friedman Rule would require, among other conditions, that the consumption of tradable and non-tradable goods could be taxed at different rates — so that the implementability constraint (14) could be dropped from the Ramsey problem.

Besides the Friedman Rule with constant tax rates, there are several other attainable policies. In example 3 the exchange rate is fixed at whenever the economy hits state \(a\) twice in a roll and devalues 34% otherwise, while the labor income taxation is constant at 20%. In example 4 there are no taxes on labor income and the exchange rate devalues 180% every period.

Example 3 (benchmark economy: fix at \((a, a)\)) The policies

\[
\left( \hat{E}(s^{t+1}), \tau(s^{t+1}) \right) = \begin{cases} 
(0\%, 20\%) & \text{if } (s_t, s_{t+1}) = (a, a); \\
(33.99\%, 20\%) & \text{if } (s_t, s_{t+1}) = (a, b); \\
(33.99\%, 20\%) & \text{if } (s_t, s_{t+1}) = (b, a); \\
(33.99\%, 20\%) & \text{if } (s_t, s_{t+1}) = (b, b);
\end{cases}
\]

can be implemented in the benchmark economy.

Example 4 (benchmark economy: constant devaluation) The constant policies \(\hat{E}(s^{t+1}) = 180.15\% \text{ and } \tau(s^{t+1}) = 0\) can be implemented in the benchmark economy.

As previously mentioned, example 1 fails to reproduce all stylized facts listed in section 2. In that example, consumption and output are negatively correlated and the real exchange rate appreciates when the economy hits state \(b\). However, a positive correlation between consumption and output and a real depreciation in times of high nominal devaluation (i.e., state \(b\)) are part of the stylized facts.

One of the goals of this section is to verify the ability of the Ramsey equilibrium to reproduce the stylized facts. A secondary goal is to obtain a better understanding of the properties of the optimal policies and the induced competitive equilibrium. To achieve these two goals several experiments were performed. Some illustrative examples will be reported below.

Example 5 (distinct transition probabilities) The economy is as in example 1, except that \(\mu_{ab} = 0.2\) and \(\mu_{ba} = 0.9\). The optimal policies are described by

\[
\left( \hat{E}(s^{t+1}), \tau(s^{t+1}) \right) = \begin{cases} 
(11.19\%, 17.90\%) & \text{if } (s_t, s_{t+1}) = (a, a); \\
(17.88\%, 17.90\%) & \text{if } (s_t, s_{t+1}) = (a, b); \\
(11.63\%, 17.96\%) & \text{if } (s_t, s_{t+1}) = (b, a); \\
(18.35\%, 17.96\%) & \text{if } (s_t, s_{t+1}) = (b, b).
\end{cases}
\]

Again, tax rates are roughly constant and the domestic currency devalues more at state \(a\) than at state \(b\).
A change in the transition probabilities affects the present value of future government expenditures. This is why optimal devaluation (as well as inflation rate) and tax rates fall when compared to example 1. Another effect is a change in the amplitude of the devaluation oscillations. The qualitative behavior of the real variables was not affected. Similar results were found with other transition probabilities.

**Example 6 (higher oscillation in $g^N$)** The economy is as in example 1, except that $g^N_a = 0$ and $g^N_b = 0.15$. The optimal policies are described by

$$\left(\hat{E}(s^{t+1}), \tau(s^{t+1})\right) = \begin{cases} 
(5.27\%, 17.76\%) & \text{if } (s_t, s_{t+1}) = (a, a); \\
(25.56\%, 17.76\%) & \text{if } (s_t, s_{t+1}) = (a, b); \\
(6.53\%, 17.96\%) & \text{if } (s_t, s_{t+1}) = (b, a); \\
(27.05\%, 17.96\%) & \text{if } (s_t, s_{t+1}) = (b, b).
\end{cases}$$

Once more, tax rates are roughly constant and the domestic currency devalues more at state $a$ than at state $b$.

The major effect of an increase in the variation of $g^N$ is to increase the oscillation in the devaluation rate of the domestic currency. The behavior of the real variables is the same as in example 1.

**Example 7 (an economy driven only by technological shocks)** The economy is identical to the one in example 1, except that $g^N_a = g^N_b = 0.075$, $\theta^N_a = 1.2$, and $\theta^N_b = 0.8$. The optimal policies are described by

$$\left(\hat{E}(s^{t+1}), \tau(s^{t+1})\right) = \begin{cases} 
(11.99\%, 22.32\%) & \text{if } (s_t, s_{t+1}) = (a, a); \\
(28.33\%, 22.32\%) & \text{if } (s_t, s_{t+1}) = (a, b); \\
(13.33\%, 22.34\%) & \text{if } (s_t, s_{t+1}) = (b, a); \\
(29.86\%, 22.34\%) & \text{if } (s_t, s_{t+1}) = (b, b).
\end{cases}$$

Once more, tax rates are roughly constant and the domestic currency devalues more at state $a$ than at state $b$.

Devaluation rate behaves as in example 1. As in that example, the ratio $\frac{g^N}{\theta^N}$ is higher in state $b$ than in state $a$. So, the relative higher public expenditures will lead to higher devaluation whenever the economy hits state $b$.

Despite the similar behavior of the exchange rate devaluation, the real variables display different qualitative patterns when compared to example 1. In the above example, both consumption and output are higher at state $a$ than at state $b$. Hence, those two variables are positively correlated.

An economy driven only by productivity shocks will display a positive correlation between consumption and output. However, this class of economy does not perform well at quantitative level. In example 7 the exchange rate oscillates at most 16 percent points and the output may increase or decrease 30%. Oscillations of this order in the output are too high.
Example 7 illustrates the main problem with an economy driven only by technological shocks. A sizable oscillation in the exchange rate devaluation will require an implausible high oscillation in the output.

The experiments performed so far suggest that a combination of negatively correlated fiscal and technological shocks is required to mimic all stylized facts. The behavior of an economy that is driven by this type of shocks is discussed below.

Example 8 (technological and fiscal shocks) Transition probabilities are $\mu_{ab} = 0.4$ and $\mu_{ba} = 0.7$. The state space is described by $g_a^N = 0$, $g_b^N = 0.15$, $\theta_a^N = \theta_b^T = 1.05$, and $\theta_b^N = \theta_b^T = 0.95$. Thus, except for the state space the economy is exactly as in example 1. The optimal policies are described by

$$(\hat{E}(s^t), \tau(s^t)) = \begin{cases} 
(5.48\%, 18.59\%) & \text{if } (s_t, s_{t+1}) = (a, a); \\
(28.18\%, 18.59\%) & \text{if } (s_t, s_{t+1}) = (a, b); \\
(6.87\%, 18.84\%) & \text{if } (s_t, s_{t+1}) = (b, a); \\
(29.85\%, 18.84\%) & \text{if } (s_t, s_{t+1}) = (b, b). 
\end{cases}$$

Tax rates are approximately constant. As before, the nominal exchange rate depreciates more at state $a$ than at state $b$.

The behavior of the real variables in example 8 mimics several of the stylized facts listed in section 2. Consider a history $s^t$ in which the last three events are equal to $(a, a, b)$. At date $t$ the rate of devaluation jumps from 5.5% to 28.2%. Consumption falls 30%, while the GDP decreases by 2%. The real exchange rate appreciates. Similar facts are observed at histories that end with $(b, a, b)$.

Consider a history in which the last three events are equal to $(b, b, a)$. At date $t$ the rate of devaluation falls from 29.9% to 6.87%. Consumption increases by 48% and GDP grows by 2%. The real exchange rate depreciates. The current account reverts from a surplus to a deficit. Similar facts are observed at histories that end with $(a, b, a)$.

Except for the behavior of the real exchange rate, the above example matches the stylized facts associated with both currency crises and pegging episodes. The reason for that relative failure of the present model will be discussed next. Consider a pegging episode. The main reason for the counter factual comportment of the real exchange rate in example 8 is the composition in the fiscal contraction. A minor reduction in $g^N$ should be accompanied by a large increase in the government revenue. In the last example the tax rate is roughly constant and the government revenue, as a percentage of the GDP, turns out to be roughly constant. Hence, all fiscal contraction (which is required to generate a large oscillation in the domestic currency devaluation rate) must take place by means of a decrease in $g^N$. Now, recall that $c_1^N + c_2^N + g^N = y^N$.

---

5 Of course, histories ending with either $(a, a, b)$ or $(b, a, b)$ are associated with currency crashes. Histories ending with either $(b, b, a)$ or $(a, b, a)$ are associated with the introduction of a currency pegging. The other possible histories are not associated with either a crash or a pegging.
The fall in $g^N$ will generate an increase in both $c_1^N$ and $c_2^N$. On the other hand, a real exchange rate appreciation requires a fall in the ratio $\frac{c_2^N}{c_T}$. But the large fall in $g^N$ will lead to a percent increase in $c_2^N$ larger than the one in $c_T$. So, the real exchange rate will depreciate instead of appreciating.

It is an interesting exercise to consider which extension of the present model could correct the counterfactual behavior of the real exchange rate. A promising approach consists in allowing $g^N$ to be produced in another sector. Observe that in the model studied in this paper the marginal rate of transformation between private and public consumption of non-tradables is constant. Thus, the increase in private consumption that takes place when $g^N$ falls is composed mostly by an increase in the private consumption of non-tradables.

4 Conclusion

Governments often choose to pursue exchange rate policies that are later abandoned. This essay shows that this pattern of behavior is efficient. A government that cares about people’s welfare will allow the rate of devaluation of the domestic currency to respond to random shocks that strike the economy.

Milesi-Ferretti and Razin [27] showed that a currency crisis is often followed by a drop below the trend of consumption and output and a real exchange rate depreciation. Kiguel and Liviatan [21] and Végh [35] provided evidence that when a country pegs the exchange rate, the opposite facts plus a current account deterioration take place.

Ideally, any model aimed at explaining the implementation and collapse of exchange rate regimes should reproduce these stylized facts. This essay succeeds in replicating most of that set of empirical regularities.

To understand the driving forces behind the selection of exchange rate policies, this paper studied the problem of choosing optimal monetary and fiscal policy with commitment in a context of exogenous government consumption and incomplete tax rates. The main finding is that the optimal devaluation rate is correlated in a positive way with government consumption and in a negative way with technological shocks. Hence, as the economy is hit by random shocks in those variables, the rate of devaluation of the domestic currency oscillates.

The optimal devaluation policy features have a simple justification. In periods of high public consumption, a benevolent government would like to increase the tax revenue. If the fiscal policy is not fully state contingent, the only remaining means to raise additional tax revenue is through inflation tax. As inflation rises, so does the devaluation rate. A negative technological shock will lead to a fall in output. Thus, the ratio between fiscal deficit and output will rise. Again, the government’s willingness to raise additional revenue explains why the devaluation is higher when there is a bad technology draw.
The model studied here is a much simpler version of those usually found in the literature on exchange rate based stabilizations. The economy lacks capital accumulation and the monetary friction was introduced by means of a cash-in-advance constraint. The study of optimal policies in a more sophisticated environment is an obvious possibility for future research.
